	Assignment No. I
	Title -> Demonstrate use of operator overloading for complex.
	class.
	Objectives:
	if To understand concept of operator overloading.
	27 To demonstrate overloading of binary operator, insertion,
1	and extraction operator.
	Problem Statement:
	Implement a class Complex which represents the complex
	Number data type. Implement the following operations:-
	1) Constructor (default including a default constructor which
	creates the complex number 0+0i)
	2) Overloaded operatort to add two complex numbers.
	8.) Overloaded operator* to multiply two complex numbers.
	4.) Overloaded << and >> to print and read complex numbers
	Ct. of Legit of participant in the contract of the
	Theory:
	C++ allows you to specify more than one defination for a
	function name or an operator in the same scope, which
	is called function overloading and operation overloading
	respectively. In overloaded declaration is a declaration
	that had been declared with the same name as a
	previously declared declaration in the same suppe, except that
	both declarations have different arguements and obviously
	different defenation (implementation). When you call an
	overloaded function or operator the compiler determines
	the most appropriate defination to use by comparing
and the second second	the argument types you used to east the function or
- The section	

operator with the parameter types specified in the definations the process of selecting the most appropriate overloaded function or operator is called overloaded resolution.

Operator overloading is one of the special feature of C++ It also shows the extensibility of C++- C++ points

permits us to add a variables of near defined types

with the same way that is expliced with built in type data type. This refers to about ability to provide special meaning for existing data types. This mechanism of giving such special meaning to an operator is known on overloading.

Operator overloading provides a flexible option for creation of new defination for most of the C++ operators. We can assign additional meaning to all existing C++ operators except following:

1) class member access operators (., .*)

2) Supe resolution operator (::)

3) Size of operator (size of)

4) Conditional operator (?:)

These operators are attributed to fact that an operator takes names as their operand instead of values.

Note: > when an operator is overloaded, its original meaning is not last. Eg. the operator + which has been overloaded to add two vectors, can stell be used to add two Phtegers.

Defination operator overloading: To define an additional task to an appearator, we must specify what it means in relation to class to which the operator is applied this is done with the help of a special function, called operator function which describes the task.

Return type class_name:: operator op (arguement list)

11 Body of function.

11 Task defined by overloaded operator.

where:

return type is type of value returned by specific operation.
op is operator being overloaded.

operator is a keywoord in C++.

operator function is no static member function or it may be friend function. A basic tiffer difference between them is that perend function will have only one arguement for unary and binary operator whereas member function has no arguement for unary operators and only one for binary operators. This is because the object used to invoke the member function is passed implicitly and therefore is available for member function. This is not the case with friend functions. Arguements may be passed either by value or by reference.

For defining an additional task to an operator, we must mention what is means in relation to the class to which it is applied. The operator function helps us to in doing so.

the syntax of declaration of an operator function is as follows:

Return type class name :: operator op (type of arguements);

for example, suppose that we want to declare an operator function for '='.

we can do it as follows:

vaid Test :: operator = (Test)

You can overload the assignment operator (=) just as you can other operators and it can be used to create an object just like the copy constitutor.

Unary operators overloading in C++: - The unary operators on a single operand and following are the examples of unary operators:

The increment (++) and decrement (--) operators.

The unaxy minus (-) operator.

The logical not (!) operator.

The unary operators operate on the object for which they were called and normally, this operator appears on the reft side of the object; as in lobj, -obj, and ++obj but sometime they can be used as prefix as well as like obj++ or obj--.

Binary operator overloading: In overloading binary operator, a friend function will have two arguements, while a member function will have one arguement.

overloading binary operators using friends: Friend functions may be used in the place of member functions for overloading a binary operator. The only difference being that a friend function requires two

arguements to be explicitly passed to if it while a member function requires only one. The same complex number program with friend function can be developed as friend complex operator + Complex, complex); and we will define this function as complex operator + (complex a, complex b) return complex (a.x+b.x), (a.y+b.y); in this case the statement & CB = CI+C2; is equal to c8 = operator + (c1, c2) In certain situation it is require using a friend function pather than member function. Rules for overloading operators:-17 Only existing operators can be overloaded. New operators cannot be overloaded. 2.7 The overloaded operator must have atteast one operand that is of user defined type 3.] We cannot change the basic meaning of an operator. That is to say, we cannot redefine the plus (+) operator to subtract one value from the other. 4.] Overloaded operators follow the syntax rules of the original operators. They cannot be overridden. 5.) There are some operators that cannot be overloaded like size of operator (sizeof), membership uperator (.), pointer to member operator (. *), scope resolution operator (::), conditional operators (?:), etc. 6) We cannot use "freed" functions to overload certain operators. However, member function can be used to overload

them Aiend functions can not be used with assignment operator(1), Function call operator(1), subscripting operator(1) class member access operator (->), etc.

Filmary operators, overloaded by means of a member function, take no explicit arguements and return no explicit values, but, those overloaded by means of a friend function, take one reference arguement (the object of the relevant et class).

8.7 Brnary operators overloaded through a member function take one explicit arguement and those which are overloaded through a friend function take two explicit arguements.

member function, the left hand operand must be an object of the relevant class.

explicitly return a value They must not attempt to change their own arguments.

Algorithm:>

1) Start the program

2.) Create a closs complex.
8.) Define default constautor.

4) Declare friend function for overloading << and >> operator.

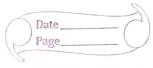

5.7 Define the overloaded function such as +, - and x-

for addition

(a+ib)+(x+iy) = (a+x)+i(b+y)

6) Create object for complex class in main()

7-) Create members for addition and multiplication of complex number

8) Accept the choice from user 9.) Depending upon the choice entered by user, the arithematic operator's will privake and print the result. 10.) Stop Howchart !-Stast. Declare Structure Read real past of 1st no imaginary part of pottno false True Read real part of 2nd no, If option tadd imaginary part of and no. false If option = add of option = mul w. realport = w. realport + we realpart wingpart = wingpart + wz. imgpart wirealpast = (wirealpart + we realpart) -(w1.imgpost + w2.imgpost) w.imapast = (wi realpost * we imapart) IF w. Imgpart >0 + (WI. imgpast * W2. realpart) Print real part true Print w. realport + w.ingport i Stop.

Conclusion: - Hence we have studied, used and and insertion-entraction operator overloading using friend function.
